objective

We add a third dimension to the Lexis diagram to account for time-to-death. This results in three *new* kinds of 2D Lexis diagrams, and a 3D Lexis diagram that is the intersection of the four *degenerate* diagrams.

(It turns out Lexis himself did something eerily similar, but not identical. Happy to explain how it works too)

The APC demographic time identity

So why more planes?

- to uncover more patterns
- to improve measurement
- to make better models
- to understand processes

So why more planes?

- to understand processes

So why more planes?

- to uncover more patterns
- to improve measurement
- to make better models
- to understand processes

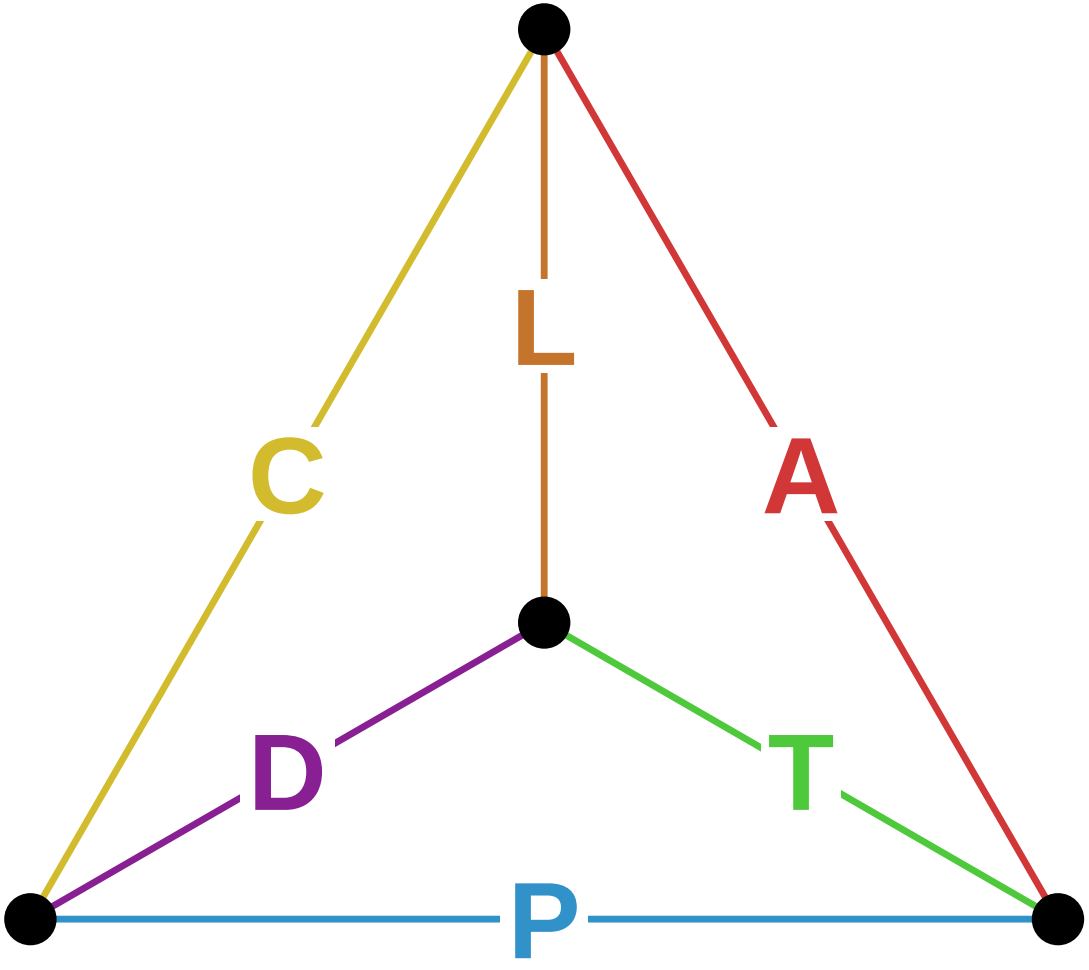
You should

- make an origami tetrahedron and label its edges with the demographic time measures
- visualize data structured in this way ASAP, because you might see new and exciting things

You should

- make an origami tetrahedron and label its edges with the demographic time measures
- visualize data structured in this way ASAP, because you might see new and exciting things

Thanks!



An example inquiry

- compare end-of-life trajectories for several birth cohorts (1905 - 1925)
- HRS (Rand), waves 1-11 (years 1992-2012)
- use TAL plane to uncover patterns that APC hides
- this example: prevalence of poor self-reported health

An example inquiry

So why more planes?

- easier to detect patterns
- to better understand the relationships between the measures of demographic time

So why more planes?
